

1 18-04-18

This research is collaboration with Prof. Yoneda from University of Tokyo.

Main equation discussed is **Navier-Stokes equation** that usually discusses in fluid, for example air.

1.1 Navier-Stokes Equation

1.1.1 General Problem

For dimension $d = 2, 3, \dots$ (usually 2 or 3) and $T > 0$, we want to find

$$(u, p) : \Omega \times (0, T) \rightarrow \mathbb{R}^d \times \mathbb{R}$$

where u is unknown velocity and p is unknown pressure such that

$$\begin{cases} \frac{\partial u}{\partial t} + (u \cdot \nabla)u - \nu \Delta u + \nabla p = f & \text{in } \Omega \times (0, T) \\ \nabla \cdot u = 0 & \text{in } \Omega \times (0, T) \\ u = 0 & \text{on } \partial\Omega \times (0, T) \\ u = u^0 & \text{in } \Omega, \text{ at } t = 0 \end{cases} \quad (1)$$

where $f : \Omega \times (0, T) \rightarrow \mathbb{R}^d$ and $u^0 : \Omega \rightarrow \mathbb{R}^d$ are given functions, $\nu > 0$ is a viscosity.

From equation (1) we can see that $\frac{\partial u}{\partial t} + (u \cdot \nabla)u$ is the **convection part** that explain the movement of fluid. This part, contain **nonlinear term** $(u \cdot \nabla)u$. We can also see, that $\nu \Delta u$ (similar to Heat equation) is the **diffusion part**. In the second equations, $\nabla \cdot u = 0$ explained the **incompressible condition** of fluid.

Incompressible condition :

$$\nabla \cdot u = \text{div } u = 0 \Leftrightarrow \text{fluid is incompressible}$$

means that the total amount of body does not change. By

$$0 = \int_V \nabla \cdot u \, dx = \int_{\partial V} u \cdot n \, ds$$

means that the energy that comes in and comes out is same and the normal component of velocity is $0 = \int_{\partial V} u \cdot n \, ds$ where n is the normal vector works on boundary.

Convection effect :

[simple explanation] Let $\phi^0(x), c > 0$ is given. Consider $\phi(x, t) = \phi^0(x - ct)$, that represent the movement of function without changing the shape.

at $t = 0$ we have $\phi(x, 0) = \phi^0(x)$; at $t = 1$ we have $\phi(x, 1) = \phi^0(x - c)$; at $t = 2$ we have $\phi(x, 2) = \phi^0(x - 2c)$ as shown above.

If we differentiate ϕ over x and t , then we obtain

$$\begin{cases} \frac{\partial \phi}{\partial t}(x, t) = \phi^0'(x - ct) (-c) = -c \phi^0'(x - ct); \text{ the initial function} \\ \frac{\partial \phi}{\partial x}(x, t) = \phi^0'(x - ct); \text{ moves to right with velocity } c \end{cases} .$$

From the above relation, we get

$$\frac{\partial \phi}{\partial t} + c \frac{\partial \phi}{\partial x} = 0.$$

If we consider velocity, $c \leftarrow u$ then $\frac{\partial \phi}{\partial t} + u \frac{\partial \phi}{\partial x} = 0$. Next, for **multidimensional convection equation**, $\frac{\partial}{\partial x} \leftarrow \nabla$, $\frac{\partial \phi}{\partial t} + (u \cdot \nabla)\phi = 0$. In Navier-Stokes equations, if we $\phi \leftarrow u_i$, then the first two term in first equation of equation (1).

[explanation] Let $u : \Omega \times (0, T) \rightarrow \mathbb{R}^d$ is given.

$$\frac{\partial \phi}{\partial t}(x, t) + [(u \cdot \nabla)\phi](x, t) = 0, \quad (x, t) \in \Omega \times (0, T).$$

Let us consider the position of a fluid particle that satisfy

$$\begin{cases} X'(t) &= u(X(t), t), \quad \forall t \\ X(t_\star) &= x \end{cases}.$$

Calculate

$$\begin{aligned} \frac{d}{dt}[\phi(X(t), t)] &= (\nabla \phi)(X(t), t) \cdot X'(t) + \frac{\partial \phi}{\partial t}(X(t), t) \\ &= [(u \cdot \nabla)\phi](X(t), t) + \frac{\partial \phi}{\partial t}(X(t), t) \\ &= \left[\frac{\partial \phi}{\partial t} + (u \cdot \nabla)\phi \right](X(t), t). \end{aligned}$$

If we set $t = t_\star$, then

$$\frac{d}{dt}[\phi(X(t), t)]|_{t=t_\star} = \left[\frac{\partial \phi}{\partial t} + (u \cdot \nabla)\phi \right](x, t_\star) = 0$$

or means that the function value does not change if it is changes by the velocity u , or called **characteristic line trajectory of particle**.

1.1.2 3D Problem

For $d = 3$, then $u = \begin{bmatrix} u_1 \\ u_2 \\ u_3 \end{bmatrix}$ such that for $(i = 1, 2, 3)$ we have

$$\frac{\partial u_i}{\partial t} + (u \cdot \nabla)u_i - \nu \Delta u_i + [\nabla p]_i = f_i$$

where

$$\begin{aligned} (u \cdot \nabla)u_i &= \left(\begin{bmatrix} u_1 \\ u_2 \\ u_3 \end{bmatrix} \cdot \begin{bmatrix} \partial_1 \\ \partial_2 \\ \partial_3 \end{bmatrix} \right) u_i \\ &= (u_1 \partial_1 + u_2 \partial_2 + u_3 \partial_3)u_i \\ &= u_1 \frac{\partial u_i}{\partial x_1} + u_2 \frac{\partial u_i}{\partial x_2} + u_3 \frac{\partial u_i}{\partial x_3} \end{aligned}$$

and

$$\Delta u_i = \frac{\partial^2 u_i}{\partial x_1^2} + \frac{\partial^2 u_i}{\partial x_2^2} + \frac{\partial^2 u_i}{\partial x_3^2}.$$

Note : we have u_1, u_2, u_3, p as four unknown functions and four equations (as first equation defined for three u and second equation), then we could find the solution.

1.2 Research Topic

We will study about axisymmetric flow (example : air). Consider cylindrical domain for first. We do two simulation, first : with the initial velocity with velocity concentration is in the center of axis, second : we include swirl, like tornado type velocity.

In this research it is proved that *if there is blow up, then there is swirl*. But has not proved that there is some blow-up phenomena ($\exists(x_\star, t_\star), t_\star < \infty$ such that $\lim_{(x,t) \rightarrow (x_\star, t_\star)} |u(x, t)| = \infty$) by Navier-Stokes.
